

Dumbledoor

Dumbledoor

2025

Named as a joke — “dumb le door” (no more) — this was a small hack to make an old intercom do slightly smarter things. I tapped into the existing intercom lines and added a tiny microcontroller so the system can detect a call, pick up simple user input (think: a short code entered at the entrance), and trigger actions — the main goal being to release the lobby door when the right code is entered.

The priority was keeping the install as non-invasive as possible: work with the existing wiring and avoid modifying the intercom itself whenever feasible - tapping the lines ended up being enough.

Build notes and details are on the Hackaday page: [Dumbledoor](#).

Notes:

- Reverse-engineer + augment legacy intercoms
- Microcontroller for detection, signal injection, and control
- Detects calls and simple keypad/code input to trigger actions
- Primary use case: open lobby door after correct code/command
- Non-invasive, compatible with existing wiring
